

## A degree 2 polynomial seems to have three distinct roots, how?

Consider the below identity:

$$\frac{(x-a)(x-b)}{(c-a)(c-b)} + \frac{(x-a)(x-c)}{(b-a)(b-c)} + \frac{(x-b)(x-c)}{(a-b)(a-c)} = 1$$

We can rearrange:

$$\frac{(x-a)(x-b)}{(c-a)(c-b)} + \frac{(x-a)(x-c)}{(b-a)(b-c)} + \frac{(x-b)(x-c)}{(a-b)(a-c)} - 1 = 0$$

Now the left side of the above can be considered as a polynomial  $P(x)$  with degree at most 2.

$$P(x) = \frac{(x-a)(x-b)}{(c-a)(c-b)} + \frac{(x-a)(x-c)}{(b-a)(b-c)} + \frac{(x-b)(x-c)}{(a-b)(a-c)} - 1$$

However,  $a, b, c$  look like three distinct roots of  $P(x)$ . **How?**

## Problem-169

Assume that  $x_1, \dots, x_{10}$  are different numbers, and  $y_1, \dots, y_{10}$  are arbitrary numbers. Prove that there is one and only one polynomial  $P(x)$  of degree not exceeding 9 such that  $P(x_1) = y_1, P(x_2) = y_2, \dots, P(x_{10}) = y_{10}$ .

**We get a set of 10 equations in 10 unknowns. As long as there is a solution, we have one polynomial. Uniqueness can be proved by reasoning about  $R(x) = P(x) - Q(x)$ .**
